Pediatric chronic kidney disease

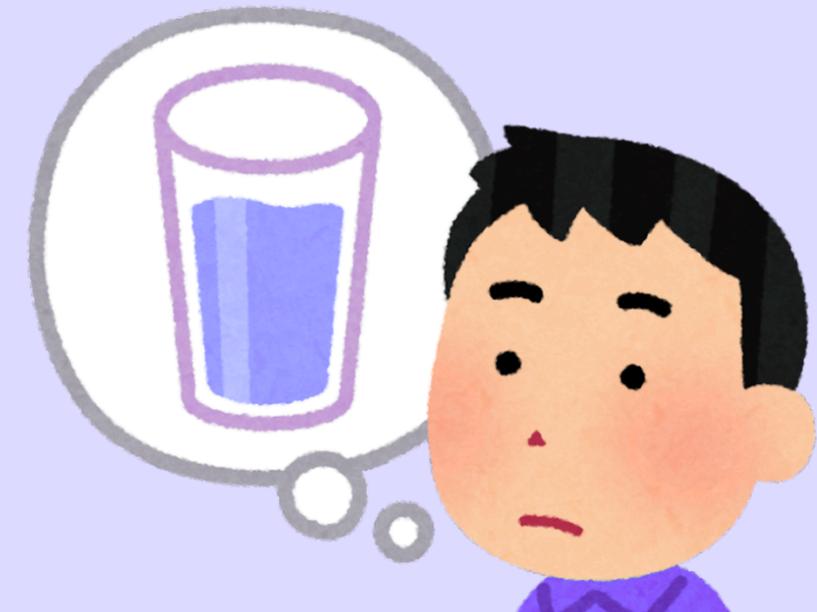

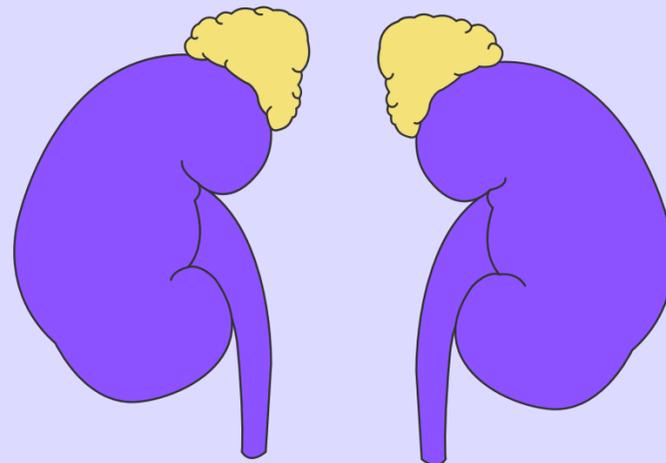

*By: Fatimah Khalid
Supervisor: Dr. Rashad Rasheed*

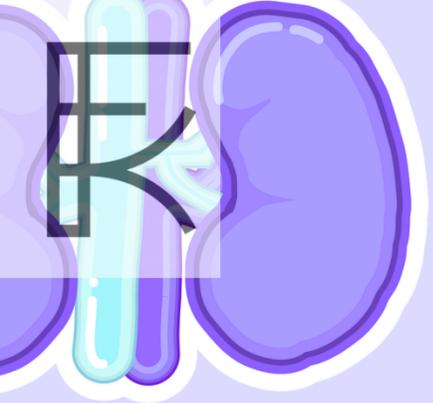

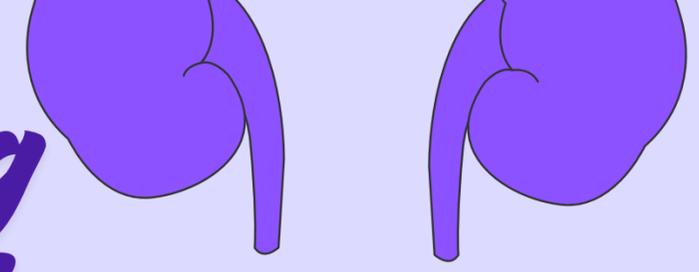

Chronic kidney disease

is a **progressive** and **irreversible** syndrome of reduction in renal capacity eventually **leading to death** when enough nephrons have been damaged.

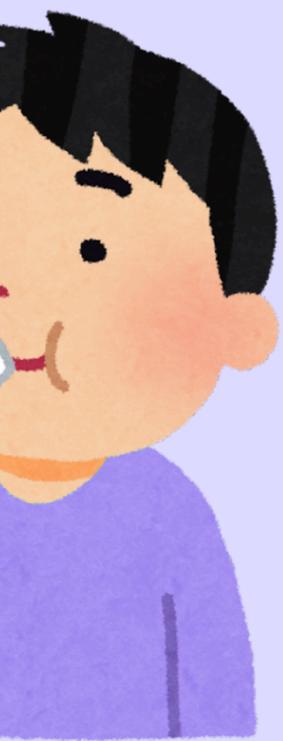

Slowing Progression

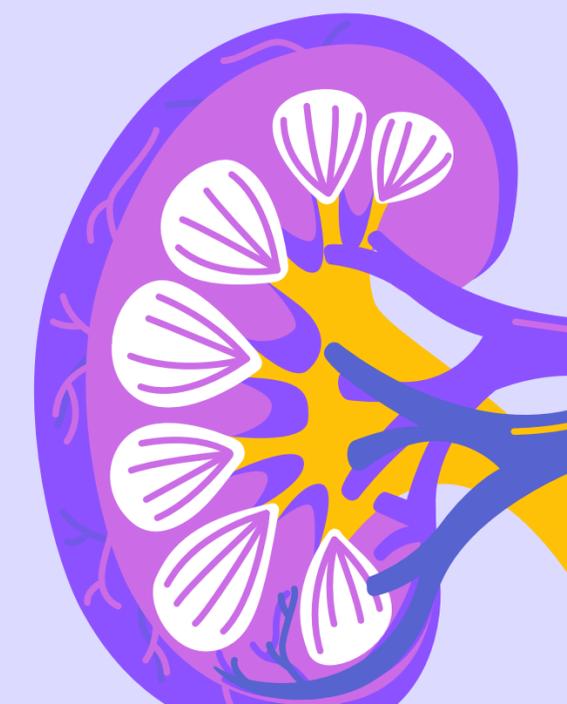

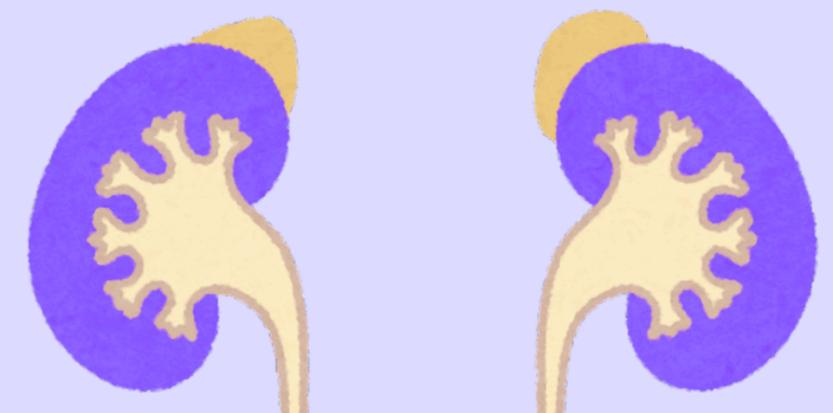

Risk Factors

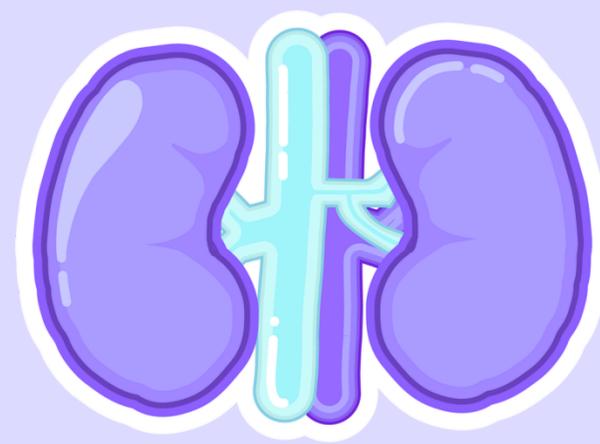

- **Identify Risks:** High blood pressure, nephrotic proteinuria, and anemia drive faster progression.
- **Anemia Impact:** Anemia is specifically deleterious for patients who do not have proteinuria.
- **Early Action:** Early diagnosis and therapy are the most critical factors in delaying CKD progression.

Early Intervention

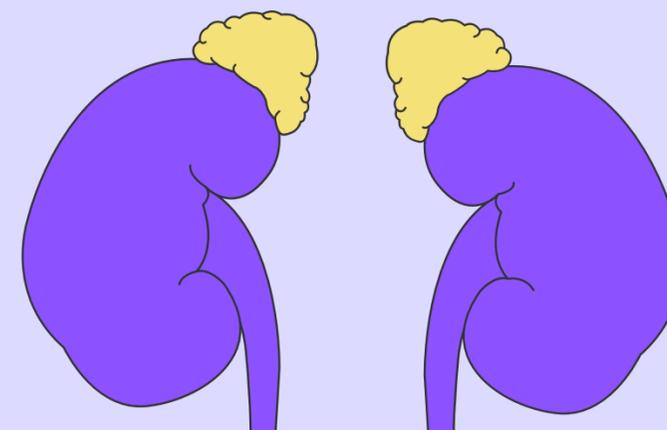

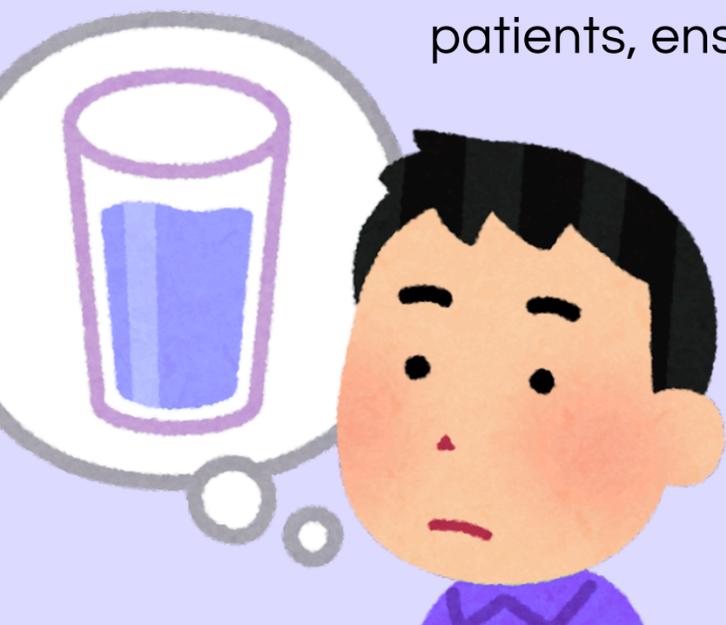

- **Iraq Specifics:** Congenital anomalies are the #1 cause of pediatric CKD in Iraq.
- **Early Detection:** Use screening and lab tests for early referral to pediatric nephrologists.
- **Acute Prevention:** Rapidly correcting severe dehydration in children under 3 years prevents acute renal failure.

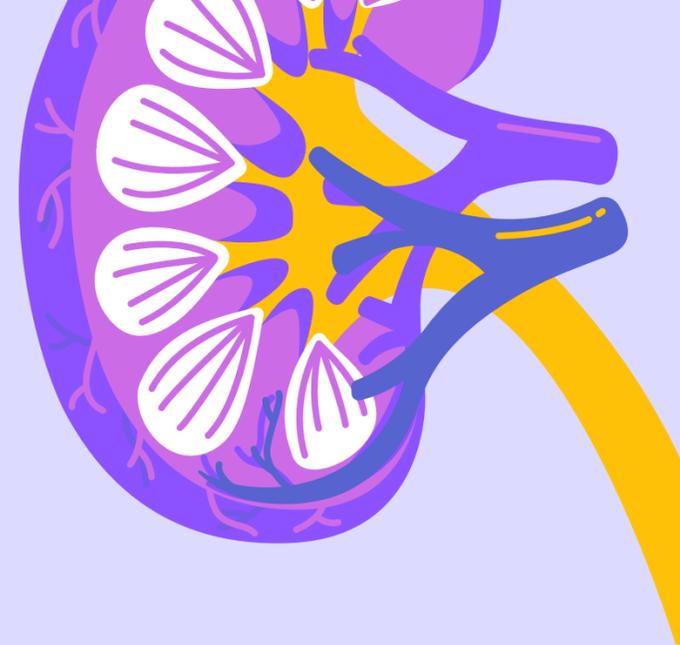

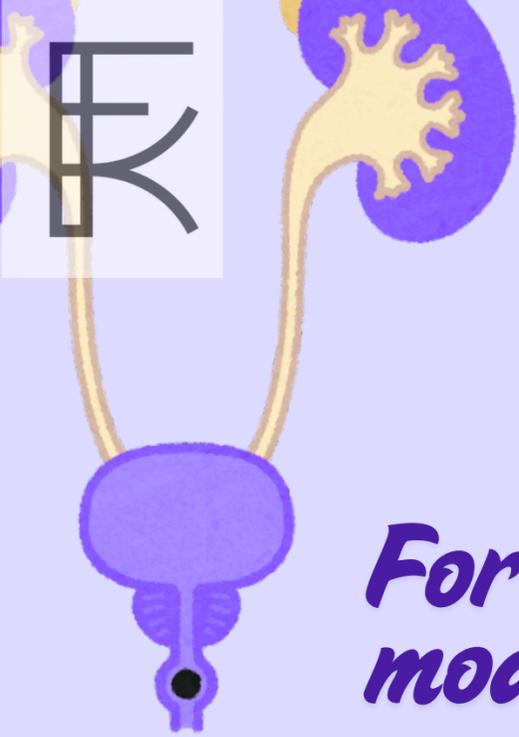

- **Hemodialysis (HD)**: The primary, effective treatment for the high ESRD burden in Iraq.
- **Growth & Nutrition**: Malnutrition is a major issue; growth failure and younger age are high predictors of mortality.
- **Tool**: Use Pediatric SGNA for accurate nutritional assessment to improve survival.
- **Holistic Care**: Success requires a multidisciplinary team for medical, nutritional, and psychological support . This comprehensive approach is essential to prevent complications and improve the lifestyle of pediatric patients, ensuring they not only survive but thrive.

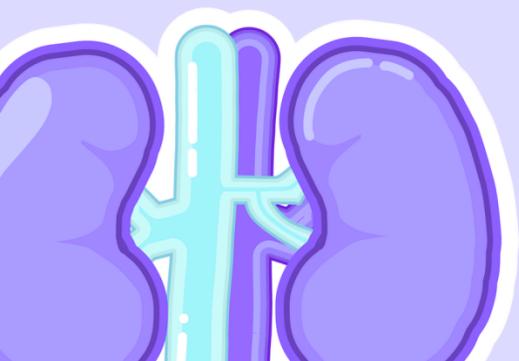

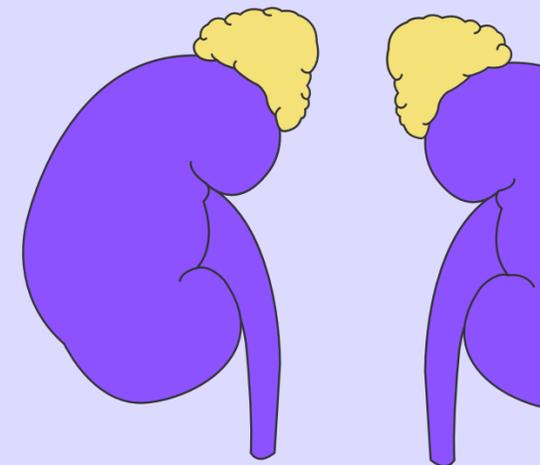

Management & Outcomes
